# Module 1-3

## Expressions, Blocks, and Logical Branching

Warren Lynch, 2019, A Comprehensive Guide to Flowchart with 50+ Examples

# Module 1 Day 3
## Can/Do you?

1.  … explain the things that can make up an Expression?
2.  … define what is meant by a *Statement* in a programming language?
3.  … describe the purpose and use of a *Block* in a programming language?
4.  … know what a *Boolean Expression* is and how it is used?
5.  … understand the *Comparison Operators* and how to use them?
6.  … understand the *Logical Operators* and how to use them?
7.  … explain casting/data conversion, when it occurs, and why it's used?
8.  … understand how () work with boolean expressions and why using them makes code more clear?
9.  … understand the Truth Table and how to use it to figure out AND and OR interactions?

# Java: Expressions

- Code is made up of expressions and statements.

- Expressions evaluate to a single value.

- Computers evaluate each expression separately.

- We use balanced parentheses to control order of evaluation or to make the order unambiguous.

  - x + y / 100    // ambiguous

  - (x + y) / 100  // unambiguous, recommended

# Java: Expressions - Booleans

- A **boolean expression** is a Logical Expression that evaluates to a Boolean true or false.

- It is used to conditionally execute blocks of code.
# Java: Statements

- Statements are roughly equivalent to sentences in natural languages.
- A statement forms complete unit of execution.
- Some expressions can be made into a statement by terminating the expression with a semicolon (;).
    - Assignment expressions          aValue = 8933.234;
    - Any use of ++ or --             aValue++;
    - Method invocations                    System.out.println("Hello World!");
- Declaration Statements      double aValue;
- Control flow statements     (... more on these later this week)

# Blocks

- Code that is related (either to conform to the Java language standard or by choice) is enclosed in a set of curly braces ( { … } ). The contents inside the curly braces is known as a "block."
- A **block** is a group of zero or more statements between balanced braces and can be used anywhere a single statement is allowed.

- Blocks are used in:
    - Conditional Statements (we will talk about this today)
    - Methods (ditto)
    - Loops

*Additional Reading on Blocks ( and Scope!)* https://www.w3schools.com/java/java_scope.asp

# Methods

- A method is a named block of code. It can accept multiple values and return a single value**.

    - Not required to accept values, but it can.

    - Not required to return a value, but it can.

- Methods have Method Signatures

    - Descriptive Names

    - Input Parameters

return-type    method-name    parameter-list

modifier ← public int max (int x, int y)
{
    if (x > y)
        return x;                    → body of the method
    else
        return y;
}

# Conditional Statements

- A conditional statement allows for the execution of code only if a certain condition is met. The condition **must be, or must evaluate to a boolean value (true or false)**.
- The if statement follows this pattern:

```
if (condition) {
        // do something if condition is true.
}
else {
        // do something if condition is false.
}
```

- The else is optional… but you cannot have an else by itself without an if.
- The parenthesis around the condition if also required.

# Conditional Statements

Here is an example:

```java
public class Bear {

    public static void main(String[] args) {

        boolean isItFall = true;

        if (isItFall == true) {
            System.out.println("ok Hibernation time zzzz.");
        }
        else {
            System.out.println("let's see what the humans are up to!");
        }
    }}
```

The == symbol means equivalence. It is not the same as =, which means assignment.

The output of this code is "ok Hibernation time zzzz. Changing isItFall to false would cause the output to be "let's see what the humans are up to!"

# Conditional Statements

Here is an example:

```java
public class Bear {

        public static void main(String[] args) {

                boolean isItFall = true;

                if (isItFall) {
                        System.out.println("ok Hibernation time zzzz.");
                }
                else {
                        System.out.println("let's see what the humans are up to!");
                }
        }}
```

Since isItFall is a boolean already, using the expression *isItFall == true* is redundant, the preferred style is shown here.

Likewise, to negate the boolean isItFall, the preferred style is to write !isItFall as opposed to isItFall == false.

# Conditional Statements

Here is another example:

```java
public class Bear {

    public static void main(String[] args) {

        String season = "Winter";

        if (season == "Winter") {
            System.out.println("ok Hibernation time zzzz.");
        }
    }
}
```

season is not a boolean, but it is used as part of an evaluation: Is the season equivalent to the literal string "Winter" .

The output of this code is "ok Hibernation time zzzz.

# Conditional Statements

Here is a tricky example. What do you think the output is?

```java
public class Bear {

    public static void main(String[] args) {

        boolean isWinter = false;

        if (isWinter = true) {
            System.out.println("ok Hibernation time zzzz.");
        }
        else {
            System.out.println("I'm starving! Time for breakfast.");
        }
    }
}
```

# Conditional Statements: Comparison Operators

The following operators allow you to compare *numbers*:

- **==** : Are 2 values equal to each other

- **!=** : Are 2 values NOT equal to each other

- **>** : Is a value greater than another value

- **<** : Is a value less than another value

- **>=** : Is a value greater or equal to another value

- **<=** : Is a value less than or equal to another value

# Conditional Statements: Numerical Comparisons

Here is an example:

```
double myTEGradeAverage = 2.3;

if(myTEGradeAverage >= 2) {
        System.out.println("I am in good standing!");
}
else {
        System.out.println("I must work harder!");
}
```

myTEGradeAverage (2.3) *is* greater than 2. This statement is true, the code block will execute.

# Conditional Statements : Ternary Operator

The ternary operator can sometimes be used to simplify conditional statements.

- The following format is used:

(**condition to evaluate**) **?** //**do this if condition is true** : //**do this if condition is false**;

- You can assign the result of the above statement to a variable if needed. The data type of this variable would be what the statements on both sides of the colon ( the **true case** and **false case**) resolve to.

# Conditional Statements : Ternary Operator Example

These 2 blocks of code accomplish the same thing.

**Ternary**

```
double myNumber = 5;
String divisbleBy2 = (myNumber%2 == 0) ? "Even" : "Odd";
System.out.println(divisbleBy2);
```

**If...Else**

```
int myNumber = 5;
String divisibleBy2 = "";

if (myNumber%2 == 0 ) {
        divisibleBy2 = "Even";
}
else {
        divisibleBy2 = "False";
}
System.out.println(divisibleBy2);
```

# AND / OR Operations: Combining Booleans

- A condition needs to be resolved into a true or false value, and we can achieve this by using the == operator.

- We can use AND / OR statements to state that code should only be executed if *multiple* conditions are true.

- The **AND** operator in Java is: **&&**

- The **OR** operator in Java is **||** (these are pipe symbols, it is typically located under the backspace and requires a shift).

# AND / OR: Truth Table

We evaluate AND / OR using truth tables:

- For AND statement:
  - **True AND True** is **True**
  - **True AND False** is **False**
  - **False AND True** is **False**
  - **False AND False** is **False**

- For OR statement:
  - **True OR True** is **True**
  - **True OR False** is **True**
  - **False OR True** is **True**
  - **False OR False** is **False**

| A | B | !A | A && B | A \|\| B | A ^ B |
|---|---|----|--------|--------|-------|
| TRUE | TRUE | FALSE | TRUE | TRUE | FALSE |
| TRUE | FALSE | FALSE | FALSE | TRUE | TRUE |
| FALSE | TRUE | TRUE | FALSE | TRUE | TRUE |
| FALSE | FALSE | TRUE | FALSE | FALSE | FALSE |

# AND / OR: Exclusive OR

There is a third case called an "Exclusive Or" or XOR for short. The operator is the carrot symbol ( ^ ).

- For XOR statements:
  - **True** XOR **True** is **False**
  - **True** XOR **False** is **True**
  - **False** XOR **True** is **True**
  - **False** XOR **False** is **False**

In most day to day programming, XOR is not used very often.

# AND / OR: Examples

```java
public class Bear {

    public static void main(String[] args) {

        String bearSpecies = "Panda";

        if (bearSpecies == "Grizzly" || bearSpecies == "Polar") {
            System.out.println("Uh Oh, I may be lunch! ");
        }
        else {
            System.out.println("Whew, Panda, I'm ok.");
        }
    }
}
```

We will branch into this if the bear species is a Grizzly or Polar Bear

The output of this code is "Whew, Panda, I'm ok."

# AND / OR: Examples

```java
int gradePercentage = 70;

if (gradePercentage >= 90) {
    System.out.println("A");
}

if (gradePercentage >= 80 && gradePercentage < 90) {
    System.out.println("B");
}

if (gradePercentage >= 70 && gradePercentage < 80) {
    System.out.println("C");
}

if (gradePercentage >= 60 && gradePercentage < 70) {
    System.out.println("D");
}
```

70 is not greater or equal to 90.
The check is false.
Statement won't execute.

70 is not greater or equal to 80 and less than 90.
The check is false.
Statement won't execute.

**70 is greater or equal to 70, and less than 80.**
**The check is true.**
**Statement will execute.**

70 is not greater or equal to 60 and less than 70.
The check is false.
Statement won't execute.

# AND / OR: Operations and Precedence

```
int myInteger = 2;

if(myInteger==2 && myInteger==3 || myInteger==4 || myInteger%2==0 || myInteger==6) {
        System.out.println("the combined statement is true.");
}
else {
        System.out.println("the combined statement is false.");
}
```

The output of this is "the combined statement is true."

- We evaluate what's inside the parentheses from left to right.
- Equality operators (== and !=) take precedence over AND (&&) / OR(||).

# Java's Order of Operations…. what we know now

| PEMDAS (Arithmetic Rules) |
|---|
| Equality Operators (**==** and **!=**) |
| AND / OR (&&, \|\|) |

Items at the top of the list take higher priority.
